

An Underwater Python: Tortuga the Python Powered Robot

Joseph Lisee

Introduction

Python Powered Robots?

- **Python**
 - ~15,000 SLOC
 - AI, GUI, Simulation, High level control
- **C++**
 - ~50,000 SLOC of C++
 - "Real time" Control, Vision, Framework
- Uses 10+ OSS libraries for support

Above: *Tortuga I* at the AUVSI AUV Competition in 2007

Robotics @ Maryland

Robotics @ Maryland

A highly self motivated group of students who love to make robots

What Does Tortuga Do?

- **Main Goal:**
 - Compete in (and occasionally win!) the AUVSI International AUV Competition
- **Functionally:**
 - Not leak
 - Drive around underwater
 - See, detect & maneuver around colored objectives
 - Home in on sounds
- **Research:** undergraduate and graduate at the SSL

Above: *Tortuga II* poised to grab the safe during an autonomous testing run

How Does it Work?

What Does Tortuga it *Really* Do?

Videos!

Glory: The Postives

Competition Success

1st place in 2008, our second year

Benefits Using Python In Robotics

Above: Testing at ~3AM July 23rd,
the night before shipping to
Tortuga II to the competition

- Great flexibility and unit testing support
 - Allows more compact code
 - Creates greater code reuse
- Easy to learn: helps to get new members up to speed
- Batteries and third party libs speed development

Great Built In Unit Testing

- No 3rd party library to install and manage
- Dynamic nature of python allowed high unit test code reuse
- Allowed refactoring as code scope increases
- Gave us actual confidence in our code (a rare thing in robotics)

Above: Joe L., Steve M., and Mike L. sweat bullets while testing at the competition

Trials & Tribulations: The Negatives

C++ Integration Woes

Above: Spaghetti mess of wiring in *Tortuga I*, similar to the elegance of our C++ integration

- Boost.Python & Py++ are powerful, but complex
- Overhead for such wrappers is large in terms of dependencies, disk space, and compile time
- Small bugs and compiler incompatibilities lead to "fragile" bindings

The GIL

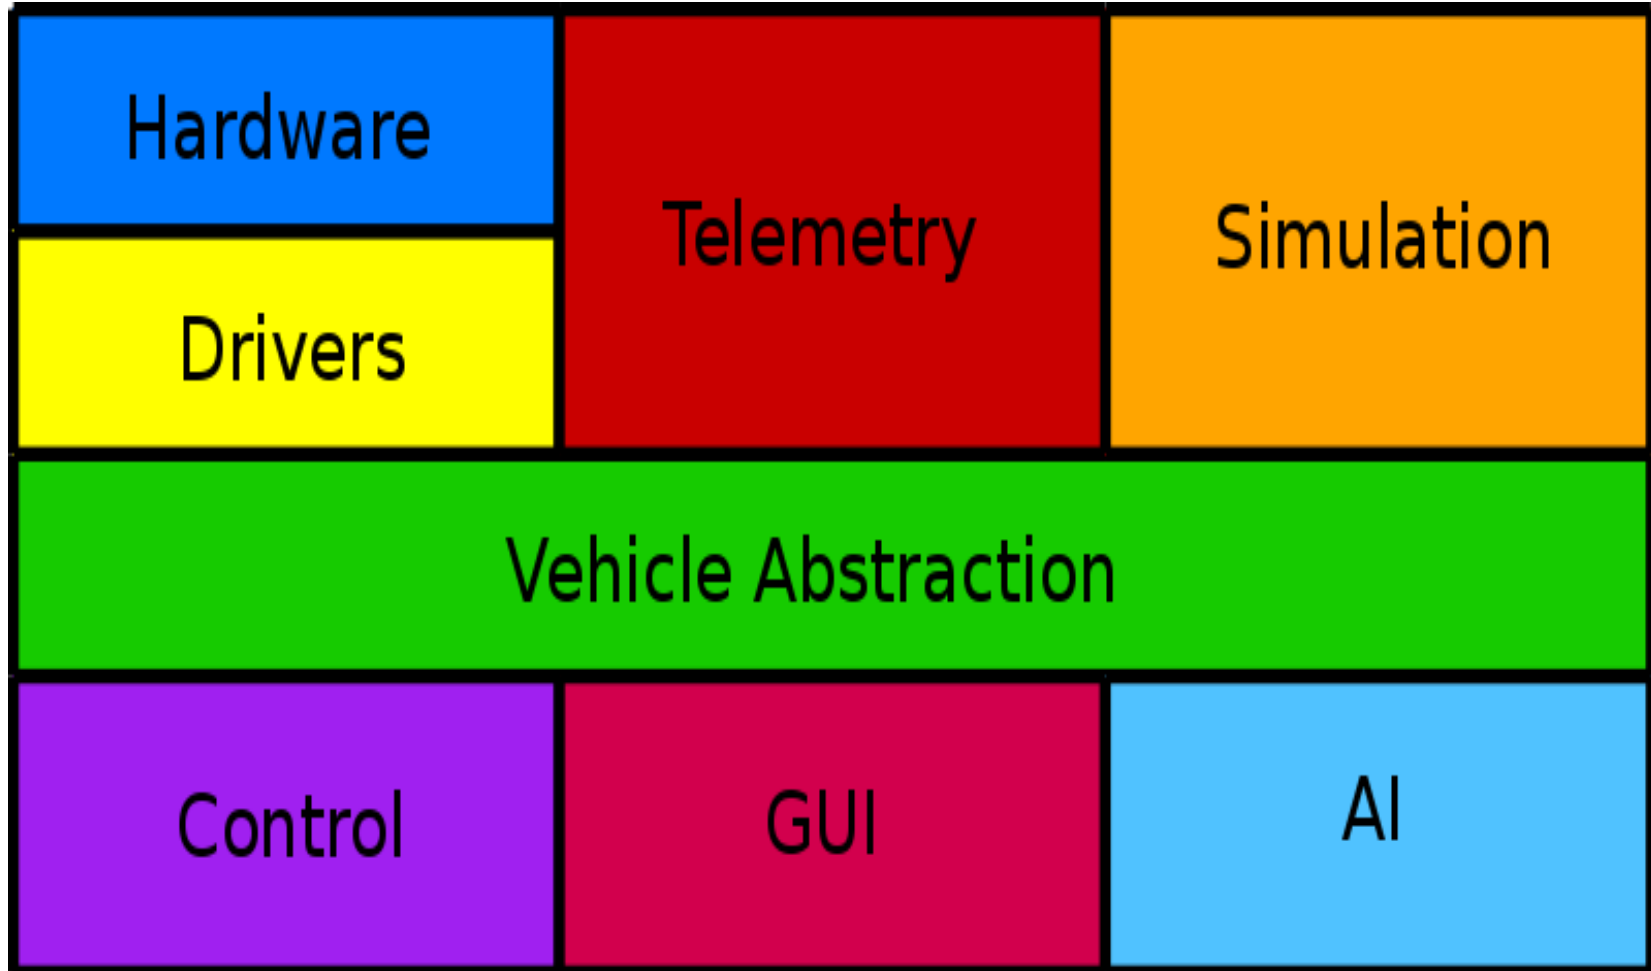

- Inflexible nature greatly constrains concurrent system design
- Forced the core of our software into C++
- C++ calling back into python is especially likely to run afoul of the GIL

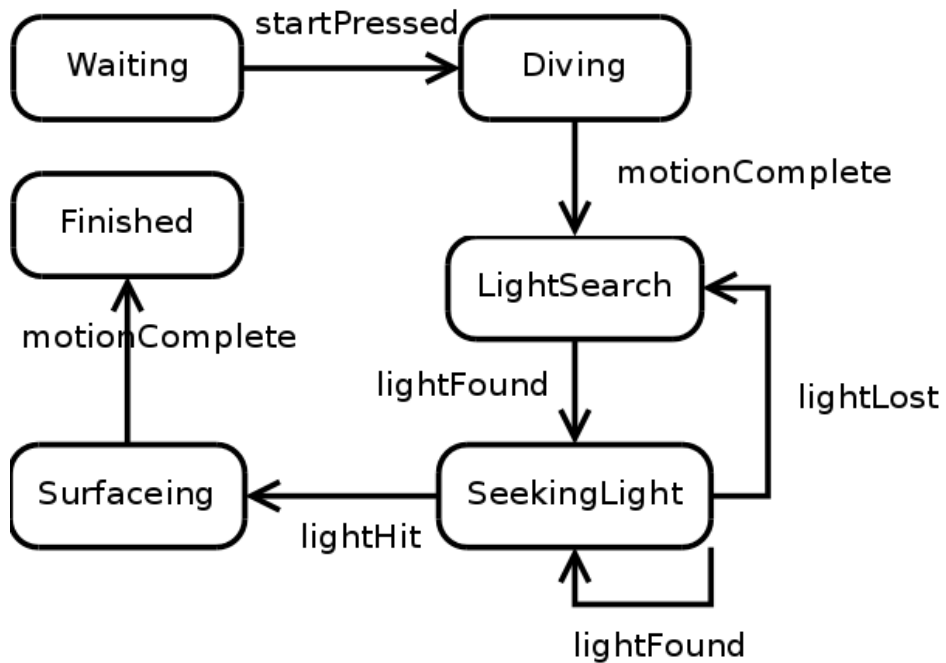

Above: The polar opposite of the GIL, Dave the judge, frustratingly flexible in his interpretation of the rules

Software

Overall System Breakdown

Artificial (Semi)Intelligence

Above: Diagram of basic state machine which seeks and hits a light

- Encoded in a pure python state machine
- Blocks are states, arrows are event driven transitions
- Easy to adapt and change after testing
- Release as the StatePy on PyPi!

GUI & Simulator

The image displays a complex GUI for a simulator, organized into several functional panels:

- Control Panels (Left):** Includes 'Vision' (Boyu, Orange Pipe, Bin), 'Target', 'BarbedWire', 'Pinger', and 'Orientation' (Roll, Pitch, Yaw) controls with numerical input fields and status indicators.
- Shell Window (Middle-Left):** A terminal window showing the current subsystems and a command prompt. The subsystems listed are:

```
Current Subsystems:  
ai: <class 'ram.ai.subsystem.AI'>  
simulation: <class 'sim.subsystems.Simulation'>  
eventHub: <class 'ext_core.EventHub'>  
timerManager: <class 'ram.timer.TimerManager'>  
queuedEventHub: <class 'ext_core.QueuedEventHub'>  
vehicle: <class 'ext_vehicle.IVehicle'>  
visionSystem: <class 'sim.vision.SimVision'>  
simSonar: <class 'sim.sonar.SimSonar'>  
controller: <class 'ext_control.IController'>  
motionManager: <class 'ram.motion.basic.MotionManager'>  
stateMachine: <class 'ram.ai.state.Machine'>  
keyboardController: <class 'sim.control.KeyboardController'>
```

The shell prompt shows the execution of `ai.start()`.
- Depth Control (Middle-Right):** A panel with 'Des:' and 'Act:' fields, both set to 9.1.
- AI Status (Bottom-Middle-Right):** Displays 'Current Task' (00:30.46), 'Current State' (00:08.62), and a list of 'Previous States' including Centering, Seeking, Searching, Start, PipeBarbedWire, and Centering.
- 3D Simulation (Right):** A top-down view of a circular arena with a blue background, a central ship icon, and a pink dotted path. Below it is a 3D perspective view of the ship's interior.
- Event Rate Table (Bottom-Left):**

Event Rate	Value
AT_ORIENTATION	7.03
BIN_FOUND	32.00
DEPTH_UPDATE	28.78
DESIRED_ORIENTATION_UPDATE	7.03
FORCE_UPDATE	175.85
MULTI_BIN_ANGLE	6.91
ORIENTATION_UPDATE	28.79

Above: Sim & Control interface done in wxPython & Python-Ogre

System Buildout

Above: *Tortuga I* at end of the 4 hour assembly at the 2007 competition

- Reduces start-up on new systems, a huge barrier for new developers
- Relies on pre-built dependencies for each platform
- Minimal use of native OS packages
- Places all files into a single directory (usually `/opt/ram/local`)
- Done with a single buildit based program upon first checkout

Dependency Management

- R@M uses ~20 open source tools and libraries
- SVN vendor branches
 - All deps in source R@M tree
- Build and package each dependency with builit
- Manual upload to the server in platform based file tree
- Dependence on target platforms to be kept to a minimum
- Makes OS upgrades easy because you keep the same version of almost all dependencies

Above: Steve M. uses a screen-less laptop to remotely use his keyboard-less laptop to reprogram electronics

Conclusion

Above: First successful test of our custom electronics (before we fried them in the vehicle)

- Dynamic languages great fit for dynamics problems
- Python let us develop more functionality then a pure C++ would of
- Python let new developers contribute faster
- Competitions and Robotics are lots of fun, but so much more work then normal software

Thanks To These OSS Projects
